Face Detection

Face Recognition

Face Field uses the EigenFaces methodology for face recognition.

- The algorithm is analyzing how pixels are distributed.
- The algorithm classifies the images in different ways that are called dimensions.
- Some examples of dimensions in face recognition are: an analysis of areas of facial hair, pose, position of eyes, cheekbones, nose and mouth.
- You can compute an average face which is neutral across all the faces in a database.
- One can build an anti-face by taking the opposite setting in each dimension.
- The algorithm uses this classification system to find similar faces and thereby to perform face recognition.
- Since the algorithm is actually analyzing the picture, not the face, it has trouble doing face recognition if lighting and pose are not consistent.

Description

View your anti-face. This is a mathematical construct that analyzes your face in 60 different dimensions and then takes the opposite setting of each of these 60 settings. The result is surprising and thought-provoking.

This is all complete and running now.

Technology

Face Recognition and Detection is implemented via OpenCV. OpenCV (Open Source Computer Vision Library) is an open source computer vision and machine learning software library. OpenCV was built to provide a common infrastructure for computer vision applications and to accelerate the use of machine perception in the commercial products.

The server runs on .net and is hosted by AppHarbor. Amazon S3 and SQL Server are used for storage. The iPhone/iPad app runs on iOS of course. Source code control is via git/github.
